IL-6 Triggers Cell Growth via the Ras-Dependent Mitogen-Activated Protein Kinase Cascade

Atsushi Ogata, Dharminder Chauhan, Gerrard Teoh, Steven P. Treon, Mitsuyoshi Urashima, Robert L. Schlossman, and Kenneth C. Anderson

IL-6 mediates growth of some human multiple myeloma (MM) cells and IL-6-dependent cell lines. Although three IL-6 signaling pathways (STAT1, STAT3, and Ras-dependent MAPK cascade) have been reported, cascades mediating IL-6-triggered growth of MM cells and cell lines are not defined. In this study, we therefore characterized IL-6 signaling cascades in MM cell lines, MM patient cells, and IL-6-dependent B9 cells to determine which pathway mediates IL-6-dependent growth. IL-6 induced phosphorylation of JAK kinases and gp130, regardless of the proliferative response of MM cells to this growth factor. Accordingly, we next examined downstream IL-6 signaling via the STAT3, STAT1, and Ras-dependent mitogen-activated protein kinase (MAPK) cascades. IL-6 triggered phosphorylation of STAT1 and/or STAT3 in MM cells independent of their proliferative response to IL-6. In contrast, IL-6 induced phosphorylation of Shc and its association with Sosl, as well as phosphorylation of MAPK, only in MM cells and B9 cells that proliferated in response to IL-6. Moreover, MAPK antisense, but not sense, oligonucleotide inhibited IL-6-induced proliferation of these cells. These data suggest that STAT1 and/or STAT3 activation may occur independently of the proliferative response to IL-6, and that activation of the MAPK cascade is an important distal pathway for IL-6-mediated growth.

The Journal of Immunology, 1997, 159: 2212-2221.

Interleukin-6 is a multifunctional cytokine that induces B cell differentiation, as well as proliferation of human multiple myeloma (MM) cells and IL-6-dependent cell lines. Specifically, it is an autocrine and paracrine growth factor for some human MM cells (1, 2). Kawano and colleagues initially postulated an autocrine growth mechanism, since MM cells secrete and specifically proliferate to IL-6 in vitro (1). More recently, triggering of MM cells via cell surface CD40 has induced IL-6-mediated autocrine MM cell growth (3, 4). On the other hand, IL-6-mediated paracrine MM cell growth is supported by the observations that bone marrow stromal cells (BMSC) are the major source of IL-6 in MM (2, 5, 6), that freshly isolated MM cells cultured without exogenous IL-6 rapidly stop proliferating (7), and that adhesion of MM cells to BMSC up-regulates IL-6 secretion by BMSC (8, 9). Most recently, IL-6 has also been demonstrated to inhibit MM cell apoptosis triggered by corticosteroids, serum starvation, and anti-Fas (10-12).

IL-6 specifically binds to a cell surface receptor consisting of two subunits, the ligand-binding gp80 IL-6R and the signal-transducing gp130 components (13). Binding of IL-6 to IL-6R induces homodimerization of gp130 and activation of the JAK (Janus kinase) family of tyrosine kinases, JAK1, JAK2, and/or Tyk2 (14-18); activated JAK family kinases phosphorylate gp130 (17). Following activation of these tyrosine kinases, three downstream pathways have been reported (19, 20). First, the phosphorylated gp130 binds to STAT3, which is phosphorylated by JAK family kinases; homodimers of phosphorylated STAT3 rapidly migrate to the nucleus and bind to IL-6 response elements on the promotor of IL-6-induced genes (18, 21-26). Second, IL-6 phosphorylates STAT1, and heterodimer of tyrosine-phosphorylated STAT1 and STAT3 binds the nuclear DNA sequence termed GAS (IFNγ-activated sequence) or SIE (sis-inducible element) (16, 18, 27-30).

Finally, IL-6 can also activate the Ras-dependent mitogen-activated protein kinase (MAPK) cascade, with sequential activation of Shc (Src homology 2α-collagen related), Grb2, Son of sevenless 1 (Sosl), Ras, Raf, MEK, and MAPK; this cascade ultimately leads to activation of transcription factors NF-IL-6 or AP-1 complex (Jun/Fos) (31-36). Recent reports have demonstrated that STAT3 activation is a critical step in differentiation and growth arrest of the M1 murine myeloid leukemia cell line (37, 38), and that STAT3 also mediates inhibition of apoptosis (39). However, which of these cascades mediates IL-6-dependent MM or cell line growth has not been delineated.

In the present study, we examined activation of IL-6 signaling cascades in patient MM cells, MM-derived cell lines, and IL-6-dependent B9 cells. Activation of STAT1 and/or STAT3 in response to IL-6 was demonstrated in cells that proliferate in response to IL-6, as well as in IL-6-dependent B9 cells. In contrast, IL-6 triggered activation of the Ras-dependent MAPK cascade, evidenced by phosphorylation of Shc, coimmunoprecipitation of phosphorylated Shc with Sosl1, and phosphorylation of Erk2 (MAPK) was observed only in B9 cells and MM2 patient cells, both of which proliferate in response to IL-6. Moreover, MAPK antisense (but not sense) oligonucleotide (ODN), which specifically abrogates MAPK protein expression and kinase activity, inhibited proliferation of B9 cells and MM patient cells triggered by IL-6. In contrast, neither p38 nor JNK1 kinase activities in B9 cells...
were altered by treatment with IL-6 or MAPK antisense ODN. These data suggest that IL-6-triggered proliferation of MM cells and B9 cells can be mediated via the MAPK cascade.

Materials and Methods

MM cells and MM-derived cell lines

MM cells (99% CD38+CD45RA−) were obtained from the peripheral blood of a patient with plasma cell leukemia (MM1), and from a malignant pleural effusion in a patient with multiple myeloma (MM2). Mononuclear cells were isolated by Ficoll-Hypaque density-gradient centrifugation, washed, and resuspended in RPMI 1640 media (Meditech, Washington, DC) containing 10% FBS (PAA Laboratories, Newport Beach, CA), ρ-glutamine, 100 U/ml penicillin, and 100 U/ml streptomycin. The OCI-MY5 human MM cell line (46) kindly provided by Dr. H. A. Messner, Ontario Cancer Institute, Toronto, Canada) was maintained in Iscove’s modified Dulbecco’s medium containing 10% FBS, ρ-glutamine, 100 U/ml penicillin, and 100 U/ml streptomycin. The B9 murine IL-6-dependent hybridoma/plasmacytoma cell line (47) (kind gift of Dr. Lucien Aarden, The Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands) was maintained in RPMI 1640 media supplemented with 10% FBS, 50 μM 2-ME (Sigma Chemical Co., St. Louis, MO), ρ-glutamine, 100 U/ml penicillin, 100 U/ml streptomycin, and 1 mg/ml L-glutathione (Genetics Institute, Cambridge, MA).

Reagents

The anti-gp130, JAK1, JAK2, Stat3, and anti-phosphotyrosine 4G10 Abs were obtained from Upstate Biotechnology (Lake Placid, NY). The anti-JAK2, Sbc, Erk1, and Erk2 Abs were purchased from Santa Cruz Biotechnology (Santa Cruz, CA). The anti-STAT3 Ab (22) was kindly provided by Dr. Shizuo Akira (Institute for Molecular and Cellular Biology, Osaka University, Osaka, Japan).

Assays of DNA synthesis

DNA synthesis of MM cells was stimulated by IL-6 as measured by thymidine ([3H]Tdr) incorporation. Briefly, 1 × 10⁴ cells in 200 μl of RPMI 1640 media without FBS were cultured for 48 h in 96-well plates in the presence or absence of 100 ng/ml of IL-6. Cells were labeled with 1 μCi/well of [3H]Tdr (sp. act., 603.1 GBq/mmol) (DuPont, Wilmington, DE) during the last 6 h of culture, harvested onto glass filters with 0.45 μm-pore size (NEN, Boston, MA) and counted on a 1205 BETAPLATE (Wallac, Finland). Proliferation was defined by the stimulation index (SI): ([3H]Tdr uptake of sample in media plus IL-6)/[3H]Tdr uptake of control sample in media alone.

Immunoprecipitation and immunoblotting

For immunoprecipitation experiments, 2 × 10⁴ cells were cultured for 1 h in the absence of serum and growth factors. After 1-h incubation with 1 mM sodium o-vanadate (Sigma Chemical Co.), cells were stimulated with 100 ng/ml of IL-6 for 30 min at 37°C. Cells were then washed twice with ice-cold Tris-buffered saline containing 1 mM sodium orthovanadate and resuspended for 30 min at 4°C in 1 ml of lysis buffer: 0.5% Nonidet P-30, 10 mM Tris-HCl, pH 7.6, 150 mM NaCl, 5 mM EDTA, 2 mM sodium o-vanadate (Na3VO4), 1 mM PMFS, 5 μg aprotinin/ml, and 1 mM Na3VO4. The 90 minute IL-6-dependent, hybridoma/plasmacytoma cell line (47) (kind gift of Dr. Lucien Aarden, The Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands) was maintained in RPMI 1640 media supplemented with 10% FBS, 50 μM 2-ME (Sigma Chemical Co., St. Louis, MO), ρ-glutamine, 100 U/ml penicillin, 100 U/ml streptomycin, and 1 mg/ml L-glutathione (Genetics Institute, Cambridge, MA).

ODN treatment of cells

Antisense strategy for depleting MAPK was described previously (48). Antisense ODN with the sequence 5’-ATG GCC GCG GCC GCC GC-3’ was synthesized on an automated DNA synthesizer (DFCI Molecular Biology Core Facilities, Boston, MA). Two hundred microliters of either sense or antisense ODN (1 μM) were added to RPMI 1640 (170 μl) and Lipofectin solution (30 μl) (Life Technologies, Grand Island, NY), and incubated at room temperature for 15 min. This mixture was added to the cells for 5 h at 37°C in the presence of 5% CO2. Then, cells were washed and suspended in media with ODN, but without Lipofectin solution, and ODN replaced every 24 h. Total cell lysates of B9 and MM2 cells after 24-h incubation were analyzed for Erk2 expression using anti-Erk2 Ab (Transduction Laboratories, Lexington, KY). For proliferation assays, 1 × 10⁴ cells/200 μl were cultured with serial doses of IL-6 for 48 h. Cells were pulsed during the last 12 h of 48-h cultures with 1 μCi of [3H]Tdr, harvested onto glass filters, and counted on a scintillation counter.

Immune complex kinase assays

In vitro kinase assays were performed as previously described (49). Lysates were preclreated by incubating with 5 mg/ml of rabbit anti-mouse IgG for 1 h at 4°C, and then for an additional 30-min incubation with protein A Sepharose CL-4B. The supernatants were incubated with preimmune rabbit serum or specific Abs for MAPK, p38, or JNK1 kinase for 2 h at 4°C before the addition of protein A Sepharose CL-4B. The immune complexes were washed three times with lysis buffer and once with kinase buffer, and resuspended in kinase buffer containing [γ-32P]ATP (3000 Ci/mmol) and DTT to 1 mM final concentration. For kinase assays, 200 μl of cell lysate (100,000 cell/μl) and 1 μCi [3H]Tdr were added to RPMI 1640 media without FBS, 50 μM 2-ME (Sigma Chemical Co., St. Louis, MO), ρ-glutamine, 100 U/ml penicillin, 100 U/ml streptomycin, and 1 mg/ml L-glutathione (Genetics Institute, Cambridge, MA).

Results

Effects of IL-6 on proliferation of patient MM cells, as well as MM-derived cell lines

The effect of IL-6 on DNA synthesis by MM patient cells, as well as MM-derived cell lines, was analyzed by [3H]Tdr uptake. As shown in Table 1, B9 IL-6-dependent cell line showed significant increases in proliferation (SI 6.9, p < 0.005) in response to IL-6 (100 ng/ml). MM2 patient cells similarly proliferated to IL-6 (SI 3.3, p < 0.005). No significant change in DNA synthesis was observed in the presence of IL-6. As shown in Table 1, B9 IL-6-dependent cell line showed significant increases in proliferation (SI 6.9, p < 0.005) in response to IL-6 (100 ng/ml). MM2 patient cells similarly proliferated to IL-6 (SI 3.3, p < 0.005). No significant change in DNA synthesis was observed in the presence of IL-6. MM2 patient cells similarly proliferated to IL-6 (SI 3.3, p < 0.005). No significant change in DNA synthesis was observed in the presence of IL-6.

Effects of IL-6 on tyrosine phosphorylation of JAK family (JAK1, JAK2, and Tyk2) protein kinases

To determine whether IL-6 induces tyrosine phosphorylation of JAK family kinases, MM patient cells, as well as MM-derived cell lines, were cultured in the presence or absence of IL-6 for 30 min. Cell lysates were immunoprecipitated with Abs to JAK1, JAK2,
and Tyk2, and tyrosine-phosphorylated proteins were detected using the 4G10 anti-phosphotyrosine mAb (Figs. 1–3). JAK1 protein was present in all cell lines studied (Fig. 1B). JAK2 (Fig. 2B) and Tyk2 (Fig. 3B) proteins were present in all cell lines studied, except for MM1 patient cells. IL-6 up-regulated phosphorylation of JAK1 in RPMI 8226, B9, OCI-My5, and U266 cells (Fig. 1A). JAK2 phosphorylation was stimulated by IL-6 in MM2 patient cells (Fig. 2A). Finally, IL-6 triggered phosphorylation of Tyk2 in RPMI 8226 and B9 cells (Fig. 3A). In IM9 cell lines, JAK1 and Tyk2 were also phosphorylated slightly by IL-6. In these experiments, reprobing the blots with anti-JAK1, anti-JAK2, and anti-Tyk2 Abs, respectively, showed equal amounts of protein in both IL-6-treated and nontreated cells of each type (Fig. 1B, 2B, and 3B).

Effects of IL-6 on tyrosine phosphorylation of gp130

Gp130 is phosphorylated by activated JAK family kinases; we therefore next examined whether gp130 phosphorylation was triggered by IL-6. Gp130 protein was present in all cell lines studied (Fig. 4B). Tyrosine phosphorylation of gp130 was markedly up-regulated by IL-6 in RPMI 8226, B9, OCI-My5, U266, and IM9 cells (Fig. 4A), in which at least one of the JAK family tyrosine kinases was also phosphorylated in response to IL-6. Although IL-6 induced phosphorylation of JAK2 in MM2 patient cells, it did not trigger phosphorylation of gp130. Finally, in Hs Sultan, ARH77, and MM1 patient cells, IL-6 did not trigger phosphorylation of either JAK kinases or gp130 (Fig. 4A). Reprobing of the blot with anti-gp130 confirmed equivalent protein amounts in both IL-6-treated and nontreated cells of each type (Fig. 4B).

Effects of IL-6 on the tyrosine phosphorylation of STAT1 and STAT3

We next assayed the phosphorylation state of STAT1 and STAT3 kinases in control and IL-6-treated MM cells. As shown in Figure 5B, STAT1 protein was present in all cell lines studied. IL-6 triggered phosphorylation of both STAT1 proteins (p91 and p84) in RPMI 8226, OCI-My5, U266, and IM9 MM cells (Fig. 5A). p84...
A) Phosphotyrosine Blot

B) Tyk2 Blot

FIGURE 3. Effects of IL-6 on Tyk2 phosphorylation in MM patient cells, as well as MM-derived cell lines. Patient MM cells, as well as MM cell-derived lines, were cultured either in media alone (−) or with (+) 100 ng/ml of IL-6 for 30 min. Cell lysates from control and IL-6-treated cells were immunoprecipitated with anti-Tyk2 Ab. A, The precipitates were resolved by 5% SDS-PAGE, and phosphorylation of Tyk2 was detected by anti-phosphotyrosine Ab. B, The blot was stripped and reprobed with anti-Tyk2 Ab.

A) Phosphotyrosine Blot

B) gp130 Blot

FIGURE 4. Effects of IL-6 on gp130 phosphorylation in MM patient cells, as well as MM-derived cell lines. Patient MM cells, as well as MM cell-derived lines, were cultured either in media alone (−) or with (+) 100 ng/ml of IL-6 for 30 min. Cell lysates from control and IL-6-treated cells were immunoprecipitated with anti-gp130 Ab. A, The precipitates were resolved by 5% SDS-PAGE, and phosphorylation of gp130 was detected by anti-phosphotyrosine Ab. B, The blot was stripped and reprobed with anti-gp130 Ab.

Phosphorylation was weaker than that of p91 in RPMI 8226, OCI-My5, and U266 cells. Stripping and reprobing of the blot with anti-STAT1 Ab demonstrated equal protein amounts in both IL-6-treated and nontreated cells of each cell type (Fig. 5B).

IL-6 induced phosphorylation of STAT3 in RPMI 8226, B9, OCI-My5, and U266 MM cell lines (Fig. 6A). Two phosphorylated STAT3 bands were observed on the immunoblots of B9 and OCI-My5 cells, both of which reacted with anti-STAT3 Ab. Cytokines that activate gp130 can induce two distinct forms of STAT3 (p88 STAT3f and p90 STAT3s) (50), and the two phosphorylated STAT3 bands induced by IL-6 in B9 and OCI-My5 cell may represent STAT3s and STAT3f. Reprobing of the blot with anti-STAT3 Ab showed equal protein amounts in both IL-6-treated and nontreated cells of each cell type (Fig. 6B).

Effects of IL-6 on the tyrosine phosphorylation of Shc, association of phosphorylated Shc with Sos1, and tyrosine phosphorylation of MAPK

To determine whether Ras-dependent MAPK cascade is activated by IL-6 stimulation, we probed for activation of three proteins (Shc, Sos1, and MAPK) in this pathway. Characteristic Shc bands (p52 and p46) were intrinsically phosphorylated in U1958, Hs Sultan, ARH77, OCI-My5, and U266 cells, as well as MM1 and MM2 patient cells (Fig. 7A). IL-6 triggered phosphorylation of p52 in B9, IM9, and MM2 patient cells. Reprobing of the blot with anti-Shc Ab showed equal protein amounts in both IL-6-treated and nontreated cells of each type (Fig. 7B).

In this cascade, Sos1 associates with the adapter Grb2 protein, and the Grb2-Sos1 complex then associates with phosphorylated Shc (51). To determine whether Sos1 is associated with phosphorylated Shc, cell lysates were immunoprecipitated with anti-Sos1 Ab and then probed with anti-Shc Ab. Up-regulation of the association of Sos1 and Shc was triggered by IL-6 only in B9 and MM2 patient cells (Fig. 8A). Sos1 and Shc communoprecipitation were not observed in IM9 cells, in spite of Shc phosphorylation, suggesting a blockade in signaling between Shc and Sos1. Sos1 protein was present in all cell lines studied, except for U266 and MM1 patient cells (Fig. 8B).

To further confirm MAPK cascade activation, we probed for tyrosine phosphorylation of MAPK (Erk1 and Erk2), which is

**FIGURE 5.** Effects of IL-6 on STAT1 phosphorylation in MM patient cells, as well as MM-derived cell lines. Patient MM cells, as well as MM cell-derived lines, were cultured either in media alone (-) or with (+) 100 ng/ml of IL-6 for 30 min. Cell lysates from control and IL-6-treated cells were immunoprecipitated with anti-STAT1 Ab. The precipitates were resolved by 5% SDS-PAGE, and phosphorylation of STAT1 was detected by anti-phosphotyrosine Ab. B, The blot was stripped and reprobed with anti-STAT1 Ab.

**B) stat1 Blot**

**FIGURE 6.** Effects of IL-6 on STAT3 phosphorylation in MM patient cells, as well as MM-derived cell lines. Patient MM cells, as well as MM cell-derived lines, were cultured either in media alone (-) or with (+) 100 ng/ml of IL-6 for 30 min. Cell lysates from control and IL-6-treated cells were immunoprecipitated with anti-STAT3 Ab. A, The precipitates were resolved by 5% SDS-PAGE, and phosphorylation of STAT3 was detected by anti-phosphotyrosine Ab. B, The blot was stripped and reprobed with anti-STAT3 Ab.

Phosphorylated on threonine and tyrosine residues following mitogen stimulation (32, 52). Cell lysates were immunoprecipitated with Ab to Erk2, which cross-reacts with Erk1, and tyrosine-phosphorylated proteins were detected using the 4G10 anti-phosphotyrosine mAb. Two bands were immunoprecipitated: Erk1 (p44) and Erk2 (p42). Up-regulation of tyrosine phosphorylation of Erk2 induced by IL-6 was observed only in B9 and MM2 patient cells (Fig. 9A), confirming that the MAPK cascade was fully activated in IL-6-responsive B9 cells and MM2 patient cells (Table II). Reprobing of the blot with anti-Erk2 Ab showed equal protein amounts in both IL-6-treated and nontreated cells of each type (Fig. 9B). Similar experiments utilizing Erk1-specific Ab demonstrated that IL-6 treatment of B9 cells does not induce tyrosine phosphorylation of Erk1 (data not shown).

**Effect of MAPK sense and antisense ODN on IL-6-induced proliferation of B9 and patient MM2 cells**

To further confirm the importance of the Ras-dependent MAPK cascade in IL-6-related proliferation, we examined the effect of MAPK sense or antisense ODN on IL-6-triggered proliferation of B9 and patient MM2 cells. B9 and patient MM2 cells were cultured in media alone, as well as with MAPK sense or antisense ODN; DNA synthesis triggered by IL-6 was measured using [3H]Tdr incorporation. IL-6 (100 ng/ml) induced a fivefold and fourfold increase in proliferation of B9 cells (Fig. 10A) and patient MM2 cells (Fig. 10B), respectively, compared with cells cultured either in media or with MAPK sense ODN. In contrast, IL-6 did not induce significant increases in proliferation of B9 cells or patient MM2 cells cultured with MAPK antisense ODN. MAPK antisense ODN, but not sense ODN, inhibited Erk2 protein expression in B9 cells (Fig. 10C) and patient MM2 cells (Fig. 10D) after 48-h incubation. In contrast, STAT1 and STAT3 expression were not changed by culturing with MAPK antisense ODN.

**Effect of MAPK antisense ODN on p38 and JNK1 protein expression and kinase activities in B9 cells**

Given the potential for interaction of proteins within the MAPK family, we next examined the kinase activities of p38, JNK, and...
MAPK in IL-6-responsive B9 cells. As seen in Figure 11A (lower panel), MAPK kinase activity was increased in B9 cells cultured with IL-6. However, IL-6 did not trigger increased p38 or JNK kinase activities in B9 cells (Fig. 11A, upper and middle panels). Moreover, treatment with MAPK antisense ODN did not alter either p38 and JNK1 kinase activities (Fig. 11B) or protein expression (Fig. 11C) in B9 cells.

**Discussion**

In this study, we characterized IL-6 signaling pathways mediating cell growth in patient MM cells and MM-derived cell lines that both proliferated to IL-6 and those that did not, as well as B9 IL-6-dependent cells. We harvested cells at 30 min after IL-6 treatment, since our prior studies demonstrated activation of gp130, PTP1D, Shc, and Sos in B9 cells under these conditions (53). Although IL-6 triggered phosphorylation of JAK family kinases, gp130, STAT1, and/or STAT3 in both MM cells that proliferated to IL-6 and those that did not, IL-6 activated the MAPK cascade only in B9 cells and MM2 patient cells that proliferated to IL-6 (Table II). Moreover, proliferation of B9 cells and MM2 patient cells in response to IL-6 was inhibited by MAPK antisense (but not sense) ODN. These studies suggest that IL-6 can trigger growth of cells via the Ras-dependent MAPK cascade.

IL-6 initially triggers phosphorylation of JAK family kinases (JAK1, JAK2, Tyk2) that bind to box1 region of gp130; activated JAK family kinases then phosphorylate gp130 in a wide spectrum of cell types: BAFm130 gp130-transfected murine proB cells; ES mouse embryonic stem cells; M1 mouse myeloid leukemia cells; EW-1 Ewing tumor cells; U266 human MM cells; B9E IL-11-dependent derivatives of B9 cells; ANBL6 IL-6-dependent human MM cells; OCI-My4 IL-6-responsive human MM cells; HT1080 human fibrosarcoma cells; HepG2 hepatoma cells; and AF10 IL-6-dependent derivative of U266 cells (14–18, 28,

−, no activation by IL-6; +, significant activation by IL-6; ±, slight activation by IL-6.

In contrast, IL-6 does not trigger phosphorylation of JAK1 in cells of multiple lineages: SK-MES squamous cell lung carcinoma cells; T10D cells, an IL-11-dependent derivative of IL-6-dependent T1105 murine plasmacytoma cells; Y6 murine hemopoietic cells; 3T3-L1 mouse preadipocytes; TF1 multifactor-dependent human erythroleukemia cells; and SKW6.4 IgM-producing cells responsive to IL-6 (15–17, 33). Phosphorylation of JAK2 in response to IL-6 also varies in different cell types: JAK2 phosphorylation was triggered by IL-6 in ES, M1, BAFlm130, EW1, B9E, ANBL6, Y6, HT1080, 3T3-L1, TF1, and SKW6.4 cells (14–18, 33), but not in U266, OCI-My4, Ti0D, and AF10 cells (15, 16, 33). Finally, phosphorylation of Tyk2 induced by IL-6 was demonstrated in SK-MES, U266, B9E, ANBL6, HT1080, and HepG2 cells (14, 15, 18, 28), but not evident in EW1, OCI-My4, and T10D cells (15, 16). In our study, marked heterogeneity of JAK family kinase activation in MM cells in response to IL-6 was also observed: JAK1, Tyk2, and gp130 were phosphorylated in RPMI 8226, B9, and IM9 cells; JAK1 and gp130 were phosphorylated in OCI-My5 and U266 cells; and only JAK2 was phosphorylated by IL-6 in MM2 patient cells. Of note, gp130 was phosphorylated in response to IL-6 only in the cells in which JAK family kinases were also activated by IL-6 (RPMI 8226, U266, OCI-My5, B9, and IM9). These studies suggest that JAK family kinases are differentially activated by IL-6 in cells of various lineages, and that all JAK family kinases can phosphorylate gp130.

After phosphorylation of JAK family kinases and gp130, IL-6 signaling proceeds via the STAT3 homodimer, STAT1-STAT3 heterodimer, and Ras-dependent MAPK pathways. Previous reports showed that IL-6 induced phosphorylation of STAT3 in HepG2, M1, National Institutes of Health3T3, B9, and HT1080 cells (18, 21–23), but not in PX63AG8 MM cells (24). On the other hand, IL-6 triggered phosphorylation of STAT1 in ANBL6, HeLa, HepG2, SK-N-MC (human neuroblastoma cell line), M1, and HT1080 cells (16, 18, 25, 27, 28, 30), but not in B9E, T10D, and OCI-My4 cells (16). In our study, STAT1 phosphorylation triggered by IL-6 was demonstrated in RPMI 8226, U266, and OCI-My5 cells, whereas STAT3 was phosphorylated in these cell lines, as well as in B9 cells. These results suggest that IL-6 activates the STAT3 homodimer pathway in B9 cells and the STAT3 homodimer and/or STAT1-STAT3 heterodimer pathways in RPMI 8226, OCI-My5, U266, and IM9 cells. As noted above, IL-6 stimulated phosphorylation of gp130 in all of these cells, suggesting that phosphorylation of gp130 is essential for activation of the STAT3 homodimer or STAT1-STAT3 heterodimer pathways. In our studies, STAT1 and STAT3 phosphorylation were induced by IL-6, even in RPMI 8226, OCI-My5, and U266 cells, which do not proliferate to IL-6 and are therefore judged to be IL-6 nonresponsive. These data suggest that these cell lines have a normal STAT signaling pathway, and that STAT3 homodimer and/or STAT1-STAT3 heterodimer pathways may be activated in MM cells growing independently of IL-6. Recent reports have demonstrated that truncated form
of gp130 (box3 region deletion, IC65) induced DNA synthesis without gp130 and STAT3 phosphorylation (19). This further supports the view that gp130, as well as STAT1 and STAT3 kinase phosphorylation, may not be required for IL-6-dependent DNA synthesis.

In previous reports, IL-6 induced activation of the Ras-dependent MAPK cascade in PC12 (rat pheochromocytoma cell line), AF10, EW-1, and National Institutes of Health3T3 cells (30–35, 36), but not in SKW6.4 and MAH (sympathoadrenal progenitor cell line) cells (30, 33). The SH2 domain of the Grb2 adapter protein binds to tyrosine-phosphorylated proteins, including receptor tyrosine kinases and Shc protein, while the SH3 domains bind to the Ras guanine nucleotide exchanger factor, Sosl (51). In the current study, IL-6 induced both Shc phosphorylation and its association with Sosl, as well as Erk2 phosphorylation only in B9 and MM2 patient cells, which proliferated in response to IL-6. On the other hand, IL-6 triggered Shc phosphorylation without its association with Sosl, Erk2 phosphorylation only in B9 and MM2 patient cells, which proliferated in response to IL-6. On the other hand, IL-6 triggered Shc phosphorylation without its association with Sosl, as well as Erk2 phosphorylation only in B9 and MM2 patient cells, which proliferated in response to IL-6. These data further support the view that gp130, as well as STAT1 and STAT3 kinase phosphorylation, may not be required for IL-6-dependent DNA synthesis.

In the present studies of patient MM2 cells, we demonstrated that MAPK antisense ODN inhibited MAPK protein expression and proliferation to IL-6; however, the protein expression and kinase activities of p38 and JNK1 were not altered under these conditions. These data confirm the importance of MAPK signaling in growth, and further suggest that p38 and JNK1 do not play a complementary role.

Other reports also support a critical role for the Ras-dependent MAPK cascade in IL-6-dependent growth. For example, cAMP is known to be an inhibitor of MAPK cascade by inhibiting Raf1 activation (54), and increased cAMP inhibits IL-6-stimulated growth of IL-6-dependent 7TD1 plasmacytoma cells and IL-6-dependent subclone of U266 cells (55). In addition, transfection of mutated Ras into IL-6-dependent ANBL6 MM cell confers IL-6-independent growth (35). Finally, Hirano and colleagues most recently demonstrated, using a series of pro-B cell lines expressing chimeric receptors composed of the extracellular domain of the granulocyte CSF receptor and the transmembrane and cytoplasmic domains of gp130, that MAPK activation and STAT3 activation were important in mitogenesis and apoptosis, respectively (39).

In the present studies of patient MM2 cells, we demonstrated that MAPK antisense ODN inhibited MAPK protein expression and proliferation to IL-6; however, the protein expression and kinase activities of p38 and JNK1 were not altered under these conditions. These data confirm the importance of MAPK signaling in growth, and further suggest that p38 and JNK1 do not play a complementary role.

Of these kinases, we also assayed p38 and JNK1 protein expression and kinase activity in B9 cells cultured with MAPK antisense ODN. Treatment of B9 cells with MAPK antisense ODN inhibited MAPK protein expression and proliferation to IL-6; however, the protein expression and kinase activities of p38 and JNK1 were not altered under these conditions. These data confirm the importance of MAPK signaling in growth, and further suggest that p38 and JNK1 do not play a complementary role.

Other reports also support a critical role for the Ras-dependent MAPK cascade in IL-6-dependent growth. For example, cAMP is known to be an inhibitor of MAPK cascade by inhibiting Raf1 activation (54), and increased cAMP inhibits IL-6-stimulated growth of IL-6-dependent 7TD1 plasmacytoma cells and IL-6-dependent subclone of U266 cells (55). In addition, transfection of mutated Ras into IL-6-dependent ANBL6 MM cell confers IL-6-independent growth (35). In the present studies of patient MM2 cells, we demonstrated that MAPK antisense ODN inhibited MAPK protein expression and proliferation to IL-6; however, the protein expression and kinase activities of p38 and JNK1 were not altered under these conditions. These data confirm the importance of MAPK signaling in growth, and further suggest that p38 and JNK1 do not play a complementary role.

FIGURE 10. Effect of MAPK antisense ODN on IL-6-induced B9 cell and patient MM2 cell proliferation. After incubation with MAPK antisense ODN (●), MAPK sense ODN (○), or media alone (○), B9 cells (A) or patient MM2 cells (B) were cultured for 48 h with serial doses of IL-6. Cells were pulsed during the last 12 h with 1 μCi of [3H]TdR/well. Cell lysates from B9 cells (C) or patient MM2 cells (D) cultured with MAPK antisense ODN (AS), sense ODN (SE), and media alone (–) were immunoblotted with anti-Erk2 Ab, anti-STAT3 Ab, and anti-STAT1 Ab.
**FIGURE 11.** Effects of IL-6 and MAPK antisense ODN on p38 and JNK1 kinase activities and protein expression in B9 cells. A, B9 cells were cultured for the indicated times with 100 ng/ml of IL-6; p38, JNK1, and MAPK kinase activities were assayed for IL-6-induced Jak2 mediated signaling. B, B9 cells were treated for 48 h with MAPK antisense ODN (AS) or sense ODN (SE) before culture of cells for 30 min in media alone (−) or with 100 ng/ml of IL-6 (+). C, Cell lysates were assayed for p38 and JNK1 kinase activities. C, Cell lysates from B9 cells cultured with MAPK antisense ODN (AS), sense ODN (SE), and media alone (−) for 48 h were immunoblotted with anti-p38 and anti-JNK1 Abs.

Recent reports have demonstrated that the Sak, Hck, Fes, Btk, and Tec kinases are also involved in IL-6-induced signaling pathways in multiple cell types (56–59), and it is likely that pathways mediating IL-6 signaling will be further elucidated. Moreover, in human MM, IL-6 is not only a growth factor, but also inhibits tumor cell apoptosis (10–12, 49). Since it has been reported recently that differences in gp130-induced signaling may have distinct biologic sequelae, i.e., growth via the MAPK cascade and induction of NF-IL-6 by IL-6 (130), differential signaling likely occurs in the growth or apoptosis of tumor cells from patients with multiple myelomas.
